(¹h.bazzi21@gmail.com, ²tahmoores@um.ac.ir)

Abstract- The aim of this study was to determine the impact of some non-genetic factors on pre-weaning and post-weaning growth in Sistani goat kids. Data of growth traits of Sistani calves were collected from the Institute of Research Domesticated Animals, Zabol University in Sistan and Baluchestan province and Iran in 2008. Traits under study were birth weight (BW), weaning weight at 90 days (WW3), weaning weight at 120 days (WW4), weight at 180 days (W6), weight at 270 days (W9), weight at 365 days (W12) and average daily gains from birth to weaning weight (BW-WW), from weaning weight to 180 days (WW-W6), from 180 to 270 days (W6-W9) and from 270 to 365 days (W9-W12). General linear model with class effects of dam weight, sex, type of birth and stage of weaning was used for analyses. The average birth weight of male kids was about 3% higher than female kids. The overall means of body weight at BW, WW3, WW4, W6, W9 and W12 were 1.915, 7.796, 9.900, 15.597, 26.253 and 34.2 kg, respectively. Birth weight averaged 2.398, 2.355, 1.858 and 1.865 kg for single males and females, twin males and females, respectively. Kids had a faster growth rate from 180 to 270 days while gain 118.4 (g/d) that the average daily gain in kids decreased with the age increase from 270 to 365 days. Average pre-weaning daily gain of female was also higher than male, but there was no significant difference observed in pre-weaning gain. Heavy dam produced heavy kid (r=0.319), but later weight had no relation with dam weight. Male kids in comparison with female kids and single born kids in comparison with twin born kids had higher birth weight and weaning weight.

Keywords- Sistani goat, Pre-post-weaning, Growth traits, Environmental factors

1. INTRODUCTION

The Sistani goat is one of the meat type breeds in eastern Iran which has a dry and hot climate. A high percentage of the goat population is managed under a migratory system, utilizing the ranges as the major source of feed. To determine optimal breeding strategies to increase the efficiency of goat production, knowledge of genetic parameters for weight traits at various ages and also the genetic relationships between the traits is needed. Various environmental effects on kid growth have previously been studied in several investigations on other breeds (Bharathidhasan et al. 2009; Hermiz et al. 2009; Jimenez-Badillo et al. 2009; Soundararajan et al. 2011).

Growth dynamic of young generation may be used as one of indicators to evaluate the level of adaptation of a gene fund under conditions of a production system which is different from its origin place. Growth period of young generation unit the puberty age can be divided in to three phases: (i) maternal phase from birth to weaning, (ii) phase of development of bio physiological mechanisms of growth and individual response to environmental conditions from weaning to 6 months old and (iii) growth phase from the age of 6 months to puberty one (Kume and Hajno 2010).

Growth of kids from birth to marketing or for replacement is traits of great economic importance and required particular attention for increasing total goat productivity although weight is an important objective in selection the potential for genetic and phenotypic parameters of this trait upon which selection may be applied.

Moreover, environmental influences can be controlled and corrected to permit more accurate identification of genetic differences between individual goats (Hermiz et al. 2009; Hermiz et al. 1998; Mavrogenis et al. 1984 and Das et al. 1996).

The birth weight and early growth rate of animals are determined not only by genetic potential but also by maternal and environmental factors (Yan Zhang et al. 2009 and Mandal et al. 2006).

Production traits are affected by various non-genetic factors like sex, season, year and type of birth (Bharathidhasan et al. 2009 and Mandal et al. 2007).

Goats are known to be potential genetic resources for meat, milk, skin and fiber throughout the tropical and developing countries. They also play an important role in the socio-economic life of the people as they feature prominently in socio-cultural functions like ceremonies and religious festivities. In fact, goats play a significant role in household nutrition and food security of pastoral people (Alade et al. 2010).
Age at the time of weaning can differ very much. According to preformed research the transition to feeding only dry feed, can be implemented successfully already at 3 weeks of age (Memisi et al. 2009).

Goats comprise one of the most important domestic livestock species in Iran and play an important role in the livelihood of a large proportion of small and marginal farmers and landless laborers. Since, the goat provides a good source of meat, milk, fiber and skin, it is popularly known as the ‘poor man’s cow’ (Sadeghi et al. 2010).

Hence, an attempt has been made to know the effects of various non-genetic factors on the body weight at birth, weaning weight and pre and post weaning weight gain of Sistani goat under southeastern agro-climatic conditions of Iran.

II. MATERIAL AND METHODS

The data were collected from the research center of domestic animal of university of Zabol in 2008.

After kidding, the new-born kids were marked and weighed. The birth weight was recorded and the kids were left with their dams for sucking till weaning age at three or four months. They received ad libium fresh alfalfa and hay beginning the third week.

They consisted of birth weight and monthly weight up to 12 month of age from 81 Sistani goat kids divided in to 2 groups: group 1 contained 39 kids (18 male and 21 female) were weaned at 3 months age and group 2 contained 42 kids (18 male and 24 female) were weaned at 4 months age.

birth weight (BW), weaning weight at 90 days (WW3), weaning weight at 120 days (WW4), weight at 180 days (W6), weight at 270 days (W9), weight at 365 days (W12) were used in this study as the dependent observations kids at different age were analyzed using the following model:

\[ Y_{ijklm} = \mu + Y_i + P_j + S_k + Z_l + e_{ijklm} \]  

Where:
- \( Y_{ijklm} \) = Records of the \( n \)th animal
- \( \mu \) = the overall Mean
- \( Y_i \) = the fixed effects of the \( i \)th sex (\( i = 1 \) or 2; 1=female, 2=male)
- \( P_j \) = the fixed effect of the \( j \)th type of birth (\( j = 1 \) or 2 =Single, 2=Twin)
- \( S_k \) = the fixed effect of the \( k \)th weight of dam (\( k = 1 \) 1, 2 or 3 1=light, 2= medium 3= heavy)
- \( Z_l \) = the fixed effect of the \( l \)th time of weaning (\( l = \) group 1 or group 2 group 1 = 3months and group 2 = 4months)
- \( e_{ijklm} \) = the residual effects

III. RESULT AND DISCUSSION

Number of records (N), Least-squares means (LSM) and standard errors (SE) of BW, WW, W6M , W9M, W12M and ADG(BW-WW), ADG(WW-6M), ADG (6M-9M) and ADG(9M–12M) for Sistani goat in various fixed effects are given in Tables 1 and 2.

The overall means of BW, WW, W6M, W9M and W12M were 1.915 ± 0.046, 8.852 ± 0.209, 15.597 ± 0.297, 26.253 ± 0.535 and 34.201 ± 0.675 kg, respectively.

Birth weight range of Sistani kids were 1.823 to 2.007kg. Its range was 2.215 to 2.451 for single males and 1.958 to 2.165kg for single females. Those of twins were 1.903 – 2.356 and 1.858-2.142kg respectively.

Kids had a faster growth rate from 6 to 9 months with daily gain 118.4 (g/d) that the average daily gain in kids decreased with the age increase from 9-12 months of age.

Table 1 show that male kids were heavier than females. The average birth weight of male and female kids was 1.94 ± 0.05 and 1.88 ± 0.05 kegs respectively. Even though male kids weighed 3.09 % higher birth weight than female kids, there was no significant difference observed.

These results agree with other studies by several authors (Jimenez-Badillo et al. 2009; Amoah et al. 1996; Husain et al. 1996; Mahgoub and Lodge 1996; Alexander et al. 1999; Al-Shorepy et al. 2002; Portolano et al. 2002; Browning et al. 2004 and Liu et al. 2005).
Average pre-weaning daily gain of female was also higher than male, but there was no significant difference observed in pre-weaning gain. In this study effect of sex on pre-weaning weight gain of Sistani goat found non-significant. Similarly, Bharathidhasan et al.(2009) found no significant effect of sex on pre-weaning weight gain of Barbari goat.

Differences in sexual chromosomes, probably in the position of genes related to growth, physiological characteristics, difference in endocrinol system (type and measure of hormone secretion especially sexual hormones) lead to difference in animal growth. In relation to endocrinol system, estrogen hormone has a limited effect on the growth of long bones in females. That could be one of the reason in which females have smaller body and lighter weight against males (Roshanfekr et al. 2011 and Rashidi et al. 2008).

ADG for male kids was higher than females as it can be seen in Table 2. Differences between male and female kids were small and non-significant before weaning ( ).

Hence average pre-weaning daily gain of female was also higher than male, but there was no significant difference observed in pre-weaning gain. Similarly, Bharathidhasan found non-significant effect of sex on pre-weaning weight gain of Barbari goat.

Birth and weaning weight Kids born as singles (Table 1) were heavier than twins.

The influence of type of birth on birth weight was also highly significant (P<0.01), with single, and twin recording 2.21±0.05 and 1.61±0.06 kg, respectively. The kids born as single were significantly heavier birth weight than those born as twins. This finding was in agreement with that of Mukundan et al (1981) in Malabari and its Sannen half-breeds, Khan and Sahni (1983) in Jamunapari kids, Sheikh at al (1996) in Chingithangi kids, Malik and Kanaujia (1991) in Beetal kids, Singh et al (2000) in Beetal half-bred kids and Soundararajan et al (2006) in non-descript kids.

In general, kids body weights decreased as litter size increase. According to the results reported in the literature (Das and Sendalo 1992; Husain et al. 1996; Mahgoub and Lu 1998; Mourad and Anous 1998; Alexander et al. 1999; Al-Shorepy et al. 2002; Portolano et al. 2002; Browning et al. 2004 and Liu et al., 2005). This effect is attributed mainly to the fact that single kids do not have to compete for space or nutrients in their mother’s uterus, unlike what happens when two or three kids were developed. The type of birth did not significantly affect the weaning weight, whilst no differences were found between single and twin kids (Table 1). Despite the presence of numerical differences in the ADG, they were not statistically significant. This result agrees with results (Husain et al. 1996 and Liu et al. 2005).

Average weight for dams of light, medium and heavy groups was 27.35±0.551, 35.15±0.179 and 38.78±0.318 kg., respectively. These weights influenced kid early weights (at birth and weaning weight), but not at later ages. Significant regression of birth weight on weight of dam at kidding revealed that heavier kids were born to heaviest dams (r : 0.319), which was in agreement with the findings of Biswas et al (1990), Koul et al (1996) and Karna et al (2001).

Weight of doe at kidding significantly affect BW (P<0.01) and WW (P<0.05) and W6M, W9M and W12M (P>0.05).

As it can be seen in Table 2, kids born from dams of light had a faster growth rate from birth to 6 months old age than those which were born from heavier does.

Time of weaning had a significant effect (P <0.05 and P <0.001) on all traits studied except for 9M and 12M.

The kids weaned at 120 days of age were significantly (P <0.01) heavier by 2.13 kg than the kids weaned at 90 days of age.

The higher weight 6M and 9M of group 2 kids than group 1 kids was 1.118 and 0.597 kg., respectively.

Different periods post weaning, already at the WW until 6M, results for trends of average daily gain for kids show significant differences (p<0.01) between two groups.

IV. CONCLUSION

This study showed the importance of certain environmental factors on growth traits. The BW, W6M, W9M and W12M, as well as ADG from Birth until slaughter weight were influenced by sex, type of birth, weight of dam and time of weaning.

Moreover, the birth weight, weaning weight and growth rate of males were found to be higher than females. These weights influenced kid early weights (at birth and weaning weight), heavier does produced heavier kids indicating the influence of the mothering ability of doe. Hence, the producers should consider maternal ability for improvement of weaning weight and growth rate of kids in the population. In addition, weaning weight of kids should be considered for selection of parent stock in order to increase productivity and eventually the economic efficiency of the farm herd.

V. ACKNOWLEDGMENTS

We would like to thank the Institute of Research Domesticated Animals, Zabol University for providing a scholarship and help collect the data on the Sistani goats for this research.
